State Machines

Event Handling

# Events and I/O

**Event** An **event** is a change in the state

- ▶ Virtually all I/O processing is driven by events
  - ▶ Whether events are detected by interrupts or by polling
  - ▶ Even video graphics output may depend on events (synchronization with the vertical “movement” to avoid visual artifacts)
- ▶ Your project will also be event driven:
  - ▶ Its execution will depend on events generated by the I/O devices
    - ▶ Whether you use polling or interrupts for detecting these events.

# Event Driven Design

- ▶ This is best addressed by an **event** driven design:
  - ▶ That is a design where **flow control** is determined by the **environment** rather than the program itself
  - ▶ Essentially, the code is executed **reactively** in response to events that may occur **asynchronously** with program execution
- ▶ Event driven design is particularly common in:
  - ▶ Graphical user interfaces (GUI)
  - ▶ Embedded systems
  - ▶ Communications/network software

# Simple Event Driven Design

**Events** The types of events that the different components of the system have to handle

**Event Queues** That provide the necessary buffering so that handling of an event may occur asynchronously to its occurrence

**Event Handlers** That process each type of event

**Dispatchers** That monitor the event queues and call the appropriate event handlers

- ▶ May be implemented as a simple loop that checks for events

## Event Driven Design and Minix 3 DD Design

- ▶ We can find these elements of event driven design in the pattern used in the design of interrupt driven Minix 3 DDs

```
5: while( 1 ) { /* You may want to use a different condition
6:     /* Get a request message. */
7:     if ( driver_receive(ANY, &msg, &ipc_status) != 0 ) {
8:         printf("driver_receive failed with: %d", r);
9:         continue;
10:    }
11:    if (is_ipc_notify(ipc_status)) { /* received notificat
12:        switch (_ENDPOINT_P(msg.m_source)) {
13:            case HARDWARE: /* hardware interrupt notification
14:                if (msg.NOTIFY_ARG & irq_set) { /* subscribed
15:                    ... /* process it */
16:                }
17:                break;
18:            default:
19:                break; /* no other notifications expected: do
20:        }
21:    } else { /* received a standard message, not a notific
```

**State Machines**

Event Handling

# Event Driven Design and State Machines

- ▶ For other than simple designs, it is very helpful to use state machines in combination with event driven design
  - ▶ A state machine is useful to handle events that may depend on the state
- ▶ A state machine is itself event driven
  - ▶ The transition from one state to another depends on the occurrence of an event

## Example: Music Playing

- ▶ A music is a succession of notes each with a given duration, with silence intervals in between
- ▶ In a game, the music must be played at the same time as there is computer animation on the screen
  - ▶ The program cannot stop while a note is being played

**Problem** How can we measure the time without blocking, as in `tickdelay()` ?

**Solution** A possibility is to use:

- ▶ The periodic interruption of the RTC to measure the time, and
- ▶ A state machine to keep track of whether we are playing a note or pausing

# Example: State Machine

- ▶ Should also include:
  - ▶ The configuration of Timer 2 with the appropriate frequency
  - ▶ The output that enables/disables the speaker
- ▶ This state machine is an example of a **Mealy Machine**:
  - ▶ A state machine where the output depends **not only** on the state **but also** on the input transition
- ▶ An alternative state machine is the **Moore Machine**:
  - ▶ A state machine where the output depends **only** on the state.
  - ▶ This usually leads to extra states
    - ▶ In this (simple) case the two machines are structurally equal

## Example: State Transition Table

<b>Cur. State</b>	<b>Input</b>	<b>Next State</b>	<b>Output</b>
Play	END_TIMER	Sil	START_TIMER
Sil	END_TIMER	Play	START_TIMER

- ▶ This contains essentially the same information as the state diagram

# Example: Implementation Using the RTC's IH

- ▶ The IH needs to know whether or not there is a music being played

- ▶ The IH needs to keep more state than the state of the state machine itself

Local state E.g.:

- ▶ The timer value – may be a down counter

Global state E.g.

- ▶ The music to be played `music_t`

## (Defining a music)

```
/** Example of a music definition
 *
 * C does not have classes: use structures
 */

typedef struct {
    int freq;    // note's frequency
    int time;    // note's duration
} note_t;

typedef struct {
    int length; // number of notes in song
    int cur;    // index of next note to be played
    int pause;  // pause between notes (in ms)
    note_t *notes; // pointer to array of notes
} music_t;
```

- ▶ Plus a set of methods to simplify the design and the implementation of the system

## Example: Playing a Note and “Time” Events

```
music_t *music; // the notes queue
enum states {PLAY, PAUSE, STOPPED}; // states of the
// "playing machine"

void rtc_ih() {
    static int state = STOPPED; // current state
    static int count; // counts interrupts: keeps track of time
    ...
    if( cause & RTC_PF ) { // periodic interrupt
        switch(state) {
            case STOPPED:
                if((nt = (note_t *) music_get(music)) != NULL ) {
                    timer_load(2, TIMER_CLK/nt->freq);
                    speaker_on();
                    state = PLAY;
                    count = nt->time/RTC_PERIOD;
                }
                break;
            case PLAY:
                count--;
                ...
        }
    }
}
```

Event Driven Design

State Machines

**Event Handling**

# Event Processing

- ▶ I/O devices' events are processed by the corresponding interrupt handlers
- ▶ The IHs may be
  - Application Dependent** As in the case above of the RTC used for playing a music;
  - Application Independent** Like the code you have developed for the labs ... or may be not

# Example

Let's consider a program that plays a note in response to a key pressed in by the user on the keyboard.

**IO Devices** Keyboard, RTC (and speaker)

**Events and event handlers**

- ▶ Scancodes generated by the keyboard are handled by the KBC IH, and forwarded to the main program
- ▶ Time ticks generated by the RTC are handled by the RTC IH

**State**

- ▶ State of the “playing machine”

# Example: A Solution

- ▶ Keyboard input is handled by an application independent IH
  - ▶ Need to define an application dependent event handler
  - ▶ Need to specify how the IH “communicates” with this event handler
    - ▶ How the data received from the keyboard is passed to the event handler?
    - ▶ When is the event handler executed?
- ▶ Music playing is handled completely by the RTC IH using a state machine as done above, but with a twist:
  - ▶ The notes to play, and the silence duration, are determined by the user rather than by some “music score”.
    - ▶ Use a queue for the notes to be played rather than the  
`struct music`

## Example: Handling Events from Keyboard

```
queue_t *kbd_q; // for communication with event handler

setup_keyboard() {
    kbd_q = new_q(...); // setup queue for ih
    set_handler(KBD_IRQ, kbd_ih);
}

void kbd_ih() {
    unsigned long u;
    event |= KBD_EVT; // signal pending event
    sys_inb(RTC_DATA_REG, &u);
    q_put(kbd_q, u); // save in queue
}
```

- ▶ `kbd_ih()` is application independent
  - ▶ Can be used virtually by all applications
  - ▶ Can use the code developed in Lab 4, if ...

## Example: Handling Keyboard Events

- ▶ Application dependent processing must be performed separately
  - ▶ In principle, this code will be different for each application

```
gqueue_t *music_q; // For passing notes to the RTC IH

void handle_kbd() {
    int n;
    char c;
    q_get(kbd_q, &n); // not a critical section in Minix 3
    c = scancode2ascii(n);
    switch(c) {
    case 'q':
        exit(0);
    default:
        ...
        gq_put(music_q, note); // put note on a queue
                               // rtc_ih() will play it
        ...
    }
}
```

## Minix 3 and Application Independent IHs

```
5: while( 1 ) { /* You may want to use a different condition
6:     /* Get a request message. */
7:     if ( driver_receive(ANY, &msg, &ipc_status) != 0 ) {
8:         printf("driver_receive failed with: %d", r);
9:         continue;
10:    }
11:    if (is_ipc_notify(ipc_status)) { /* received notificat
12:        switch (_ENDPOINT_P(msg.m_source)) {
13:            case HARDWARE: /* hardware interrupt notification
14:                if (msg.NOTIFY_ARG & irq_set) { /* subscribed
15:                    ... /* process it */
16:                }
17:            ...
18:        }
19:    } else { /* received a standard message, not a notific
20:        ...
21:    }
22:    /* Now, do application dependent event handling */
23:    if ( event & KBD_EVT ) {
24:        handle_kbd();
25:    } else if ( event &
```

# Application Independent vs Application Dependent IH

## In General

- ▶ Can be reused
  - ▶ Operating systems IH is independent of applications
- ▶ Introduces a level of indirection
  - ▶ May add flexibility
  - ▶ May be more responsive
  - ▶ Requires more code
  - ▶ Has higher overhead

## In Minix 3

`driver_receive()` is a blocking call

- ▶ Application dependent processing must be done in the same loop iteration as application independent processing
  - ▶ It is not possible to delay application dependent processing until there are no interrupts to handle
- ▶ It does not afford as much flexibility as in the general case
